

1. No, the website will not be visible, instead a *403 Forbidden* message will be displayed. This message indicates that my static website is being hosted by Amazon S3, but that the content is private.

So, to make the website visible, we shall either make the whole bucket public or only the objects (html, CSS, and JS files) public inside the bucket using the Access Control List (ACL).

To enable that, we must select the three objects responsible for the website, then click on the Actions button and choose the make public option. Now the objects are made public, if we go and refresh the webpage that was showing the 403 error, we can now see the full static website visible to us.

2. There are many ways to ensure that:
 - We can use **Versioning**, this allows us to preserve, retrieve, and restore every version of every object in the stored bucket.
 - Then we can implement **lifecycle rules** which will transfer objects to different storage classes or delete them when they reach certain criteria. This helps us to manage the lifetime and the cost of storing multiple versions of the objects.
 - Implement **Cross-Region-Replication (CRR)**, CRR is an Amazon S3 feature that automatically replicates data between buckets across different AWS Regions. With CRR, we can set up replication at a bucket level, a shared prefix level, or an object level using S3 object tags. If data is critical, we can replicate your data across multiple AWS regions. In case of accidental deletion in one region, we can still retrieve the data from another region.
 - Then there is **Same-Region-Replication (SRR)**, SRR is also similar to CRR, SRR helps us address data sovereignty and compliance requirements by keeping a copy of our data in a separate AWS account in the same region as the original. We can use SRR to change account ownership for the replicated objects to protect data from accidental deletion.
3. No, the version that was deleted from the source bucket was not deleted from the destination bucket as versioning, and CRR have been implemented, which will save the same objects in different buckets from different regions and prevents the deletion of objects in the destination bucket even though it was deleted from the source bucket.

Task 1: Extracting the files that you need for this lab

In this task, you will extract the files that you need to create the static website.

5. Download the .zip file you need for this lab by opening [this Amazon S3 link](#).

6. On your computer, extract the files. Notice that

Launch Terminal

Total score 29/29
